

OPTICAL GRATING BASED MULTIPLEXER DEVICE

WITH POWER TAP CAPABILITY

Abstract of the Invention

In an optical grating device, a grating arrangement receives
5 different wavelength output signals from a plurality of radiation
sources at input ports thereof, and generates therefrom a
multiplexed wavelength output signal at a zero diffraction order
output port of the grating arrangement. Additionally, the gating
arrangement generates at least one predetermined wavelength
10 output signal at one of a group consisting of a separate
predetermined location in an at least one of a symmetric non-zero
diffraction order of the grating arrangement, within the grating
arrangement itself, and a combination thereof. A separate power
tap is coupled to detect the power of a separate one of the at
15 least one predetermined wavelength output signal from the grating
arrangement.
